

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

ing the full type series of specimens; for if these were known to the author, and deemed *S. cordata* in 1857, it would naturally be supposed that *S. balsamifera* would be left where it was placed by Hooker, even if the same plant were on another page described as a new species. It is clear that in restoring Barratt's name we are simply doing what Prof. Andersson would, or should, have done had not this oversight occurred.

P. S. I have just received a letter from Mr. Pringle announcing the discovery of *S. balsamifera* in the White Mountains; not, however, on the banks of the Ammonoosuc, where search was first made in vain, but on the Saco, where specimens were collected June 13th, having immature fertile aments and the characteristic Amelanchier-like leaves.—M. S. BEBB.

CAREX COMOSA, Boott.—On the 5th of July I collected, in the edge of the salt meadows, near Newark, N. J., a single specimen of a remarkable abnormal form of *Carex comosa*. The upper part of the culm is very slender, and bears three sessile spikes, each subtended by a long, very slender bract. Spikes four to eight inches apart, all pistillate except at the apex, where they have empty staminate scales. Upper spike loosely compound, its divisions sessile, and subtended by long (some $1\frac{1}{2}$ inches) bristle-shaped bracts, these becoming successively shorter, as their spikelets decrease in size, until they pass into the ordinary scales of the spike.—H. H. RUSBY.

POTAMOGETON.—By the will of the late Dr. J. W. Robbins, of Uxbridge, Mass., all his collections of the genus *Potamogeton* have been sent to Rev. Thos. Morong, of Ashland, Mass., for arrangement and distribution. Mr. Morong is preparing not only to do this but proposes to do some work of revision. As this will be of great use we would urge that botanists over the country send Mr. Morong specimens of the species for examination, especially any unusual forms, as a good deal of new material is already in hand for a general revision of the genus.—J. M. C.

DICHOGAMY IN RHODODENDRON MAXIMUM.—The writer does not know whether the above fact has been recorded or not, but it may be news to some. It was noticed this year in a study of the above species that the stamens mature first and are ready to shed their pollen before the pistil is even stigmatic. After a while the pistils mature and receive their pollen from other flowers through the agency of insects.—J. M. C.
